Abstract

Recent advances in deep learning have shown excellent performance in various scene understanding tasks. However, in some complex environments or under challenging conditions, it is necessary to employ multiple modalities that provide complementary information on the same scene. A variety of studies have demonstrated that deep multimodal fusion for semantic image segmentation achieves significant performance improvement. These fusion approaches take the benefits of multiple information sources and generate an optimal joint prediction automatically. This paper describes the essential background concepts of deep multimodal fusion and the relevant applications in computer vision. In particular, we provide a systematic survey of multimodal fusion methodologies, multimodal segmentation datasets, and quantitative evaluations on the benchmark datasets. Existing fusion methods are summarized according to a common taxonomy: early fusion, late fusion, and hybrid fusion. Based on their performance, we analyze the strengths and weaknesses of different fusion strategies. Current challenges and design choices are discussed, aiming to provide the reader with a comprehensive and heuristic view of deep multimodal image segmentation.

Keywords: Image fusion, Multi-modal, Deep learning, Semantic segmentation

1. Introduction

Semantic segmentation, as a high-level task in the computer vision field, paves the way towards complete scene understanding. From a more technical perspective, semantic image segmentation refers to the task of assigning a semantic label to each pixel in the image [1, 2, 3]. This terminology was further distinguished from instance-level segmentation [4] that devotes to produce per-instance mask and class label. Recently, panoptic segmentation [5, 6] is getting popular which combines pixel-level and instance-level semantic segmentation. Although there are many traditional machine learning algorithms available to tackle these challenges, the rise of deep learning techniques [7, 8] gains unprecedented success and tops other approaches by a large margin. For example, Convolutional Neural Networks (CNNs) [9] has become one of the most impressive algorithms for image-driven pattern recognition tasks. Besides, Recurrent Neural Networks (RNNs) [10, 11] are commonly used for retrieving contextual features, which remember every information through time. The various milestones in the evolution of deep learning significantly promote the advancement of semantic segmentation research.

Moreover, the availability of multiple sensing modalities has encouraged the development of multimodal fusion, such as 3D LiDARs, RGB-D cameras, thermal cameras, etc. These modalities are usually used as complementary sensors in complex scenarios, reducing the uncertainty of scene information. For example, visual cameras perform advanced information processing in lighting conditions, while LiDARs are robust to challenging weather conditions such as rain, snow, or fog. Thermal cameras work well in the nighttime as they are more sensitive to infrared radiation emitted by all objects with a temperature above absolute zero [12]. Arguably, the captured multimodal data provide more spatial and contextual information for robust and accurate scene understanding. Compared to using a single modality, multi-modalities significantly improve the performance of learning models [13, 14, 15, 16, 17].

Especially in recent years, deep multimodal fusion methods benefit from the
massive amount of data and increased computing power. These fusion methods fully exploit hierarchical feature representations in an end-to-end manner. Multimodal information sources provide rich but redundant scene information, which is also accompanied by uncertainty. Researchers engage in designing compact neural networks to extract valuable features, thus enhancing the perception of intelligent systems. The underlying motivation for deep multimodal segmentation is to learn the optimal joint representation from rich and complementary features of the same scene. Improving the accuracy and robustness of deep multimodal models is one of the significant challenges in this area. Also, scalability and real-time issues should be taken into consideration for real-world applications. As an illustration, Figure 1 shows the pipeline of deep multimodal segmentation.

Several relevant surveys already exist, such as deep learning-based semantic segmentation [2, 3, 18, 19], indoor scene understanding [20, 21], multimodal perception for autonomous driving [22], multimodal human motion recognition [23], multimodal medical image segmentation [24], and multimodal learning study [25, 26]. However, these review works are mostly focused on unimodal image segmentation, multimodal fusion for specific domains, or multimedia analysis across video, audio, and text. Especially with the advent of low-cost sensors, an increasing number of visible/invisible light and depth cameras are employed in scene understanding. There is a lack of systematic review that focuses explicitly on deep multimodal fusion for 2D/2.5D semantic image segmentation.

In summary, the main contributions of this paper are as follows:
We provide necessary background knowledge on multimodal image segmentation and a global perspective of deep multimodal learning.

We conduct an extensive literature review on existing deep multimodal fusion methods, with the highlight of their contributions to model design.

We conduct a comprehensive survey of current semantic segmentation datasets as well as the potential multimodal datasets.

We gather quantitative experimental results of multimodal fusion methods on different benchmark datasets, including their accuracy, runtime, and memory footprint.

The remainder of this paper is organized as follows. The background concepts of deep multimodal fusion for semantic image segmentation are firstly described in Section 2 including the development, recent advancements as well as related applications. Section 3 reviews the existing deep multimodal segmentation methods according to our taxonomy of fusion strategy, followed by a brief discussion on architectural design. Section 4 provides a broad survey of current unimodal and multimodal image segmentation datasets. Several typical modalities (e.g., RGB-D, Near-InfraRed, thermal and polarization cameras) are highlighted. Quantitative performance evaluations of the fusion methods mentioned earlier are summarized and analyzed in Section 5. Finally, Section 6 concludes this paper.

2. Background

Multimodal fusion systems work like the human brain, which synthesizes multiple sources of information for semantic perception and further decision making. First of all, we adopt the definition of "modality" from [27], which refers to each detector acquiring information about the same scene. Ideally, we would like to have an all-in-one sensor to capture all the information, but for most complex scenarios, it is hard for a single modality to provide complete
knowledge. The primary motivation for multimodal fusion is to obtain rich characteristics of the scenes by integrating multiple sensory modalities.

As a multi-disciplinary research area, the adopted definition of multi-modality varies in different fields. For example, in medical image analysis, the principal modalities involve Computed Tomography (CT), Magnetic Resonance Imaging (MRI), Positron Emission Tomography (PET), Single-Photon Emission Computed Tomography (SPECT) [28], to name a few. Benefiting from the complementary and functional information about a target (e.g. an organ), multimodal fusion models can achieve a precise diagnosis and treatment [29, 30, 31]. In multimedia analysis, multimodal data collected from audio, video as well as text modalities [31, 32, 26] are used to tackle semantic concept detection, including human-vehicle interaction [33], biometric identification [34, 35, 36]. In remote sensing applications, multimodal fusion leverages the high-resolution optical data, synthetic aperture radar, and 3D point cloud [37, 38].

In this survey, we clarify the definition of "modality" for semantic segmentation tasks as a single image sensor. Relevant modalities reviewed in this survey include RGB-D cameras, Near-InfraRed cameras, thermal cameras, and polarization cameras. Next, we introduce the development of semantic image segmentation from uni-modality to multi-modality and their applications for indoor and outdoor scene understanding.

2.1. Semantic Image Segmentation

There have been many studies addressing the task of semantic image segmentation with deep learning techniques [2, 39]. Fully Convolutional Network (FCN) [40] was first proposed for effective pixel-level classification. In FCN, the last fully connected layer is substituted by convolutional layers. DeconvNet [41], which is composed of deconvolution and unpooling layers, was proposed in the same year. Badrinarayanan et al. [42] introduced a typical encoder-decoder architecture with forwarding pooling indices, mentioned as SegNet. Another typical segmentation network with multi-scale features concatenation, U-Net [43], was initially proposed for biomedical image segmentation. In particular,
U-Net employs skip connections to combine deep semantic features from the decoder with low-level fine-grained feature maps of the encoder. Then a compact network called ENet [44] was presented for real-time segmentation. In the work of PixelNet, Bansal et al. [45] explore the spatial correlations between pixels to improve the efficiency and performance of segmentation models. It is worth noting that Dilated Convolution was introduced in DeepLab [46] and DilatedNet [47], which helps to keep the resolution of output feature maps with large receptive fields. Besides, a series of Deeplab models also achieves excellent success on semantic image segmentation [48, 49, 50].

Furthermore, Peng et al. [52] dedicated to employing larger kernels to address both the classification and localization issues for semantic segmentation. RefineNet [53] explicitly exploits multi-level features for high-resolution prediction using long-range residual connections. Zhao et al. [54] presented an image cascade network, known as ICNet, that incorporates multi-resolution branches under proper label guidance. In more recent years, semantic segmentation for adverse weather conditions [55, 56] and nighttime [57, 58] has also been addressed to perform the generalization capacity and robustness of deep learning models. Figure 2 shows the number of papers about segmentation published in

![Segmentation](image-url)
the past decade.

In addition to the aforementioned networks, many practical deep learning techniques (e.g., Spatial Pyramid Pooling [59], CRF-RNN [60], Batch Normalization [61], Dropout [62]) were proposed for improving the effectiveness of learning models. Notably, multi-scale feature aggregation was frequently used in semantic segmentation [63, 64, 65, 66, 67]. These learning models experimentally achieve significant performance improvement. Lin et al. [68] introduced the Global Average Pooling (GAP) that replaces the traditional fully connected layers in CNN models. GAP computes the mean value for each feature map without additional training of model parameters. Thus it minimizes overfitting and makes the network more robust. Related applications in multimodal fusion networks can be found in [69, 70, 71]. Also, the $1 \times 1$ convolution layer is commonly used to allow complex and learnable interaction across modalities and channels [72, 70]. Besides, attention mechanism has become a powerful tool for image recognition [73, 74, 75]. The attention distribution enables the model to selectively pick valuable information [76], achieving more robust feature representation and more accurate prediction.

2.2. Deep Multimodal Segmentation

Before the tremendous success of deep learning, researchers expressed an interest in combining data captured from multiple information sources into a low-dimensional space, known as early fusion or data fusion [77]. Machine learning techniques used for such fusion include Principal Component Analysis (PCA), Independent Components Analysis (ICA), and Canonical Correlation Analysis (CCA) [25]. As the discriminative classifiers [78] become increasingly popular (e.g. SVM [79] and Random Forest [80]), a growing body of research focus on integrating multimodal features at the late stage, such fusion strategy was called late fusion or decision fusion. These fusion strategies had become mainstream for a long time until the popularity of convolutional neural networks.

Compared to conventional machine learning algorithms, deep learning-based methods have competitive advantages in high-level performance and learning
ability. In many cases, deep multimodal fusion methods extend the unimodal algorithms with an effective fusion strategy. Namely, these fusion methods do not exist independently but derive from existing unimodal methods. The representative unimodal neural networks, such as VGGNet [81] and ResNet [82], are chosen as the backbone network for processing data in a holistic or separated manner. The initial attempt of deep multimodal fusion for image segmentation is to train the concatenated multimodal data on a single neural network [83]. We will present a detailed review of recent achievements in the following sections, covering various existing fusion methodologies and multimodal image datasets.

We conclude this part by pointing out three core challenges of deep multimodal fusion:

**Accuracy.** As one of the most critical metrics, accuracy is commonly used to evaluate the performance of a learning system. Arguably, the architectural design and the quality of multimodal data have a significant influence on accuracy. How to optimally explore the complementary and mutually enriching information from multiple modalities is the first fundamental challenge.

**Robustness.** Generally, we assume that deep multimodal models are trained under the premise of extensive and high-quality multimodal data input. However, multimodal data not only brings sufficient information but also brings redundancy and uncertainty. During data acquisition, image sensors have different sensitivity to scene information. The poor performance of individual modality and the absence of modalities should be seriously considered.

**Effectiveness.** In practical applications, multimodal fusion models need to satisfy certain requirements, including simplicity of implementation, scalability, real-time, etc. Moreover, ensuring network convergence can be a significant challenge with the use of redundant multimodal data.

2.3. Applications for Scene Understanding

As one of the major challenges in scene understanding, deep multimodal fusion for semantic segmentation cover a wider variety of scenarios. For instance,
Hazirbas et al. [84] address the problem of pixel-level prediction of indoor scenes using color and depth data. Schneider et al. [85] present a mid-level fusion architecture for urban scene segmentation. Similar works in both indoor and outdoor scene segmentation can be found in [70]. Furthermore, the work by Valada et al. [86] led to a new research topic in scene understanding of unstructured forested environments. Considering non-optimal weather conditions, Pfeuffer and Dietmayer [56] investigated a robust fusion approach for foggy scene segmentation.

Besides the image segmentation task mentioned above, there are many other scene understanding tasks that benefit from multimodal fusion, such as object detection [13, 87, 88], human detection [89, 14, 90, 91], salient object detection [92, 93], trip hazard detection [94] and object tracking [69]. Especially for autonomous systems, LiDAR is always employed to provide highly accurate three-dimensional point cloud information [95, 96]. Patel et al. [97] demonstrated the utility of fusing RGB and 3D LiDAR data for autonomous navigation in the indoor environment. Moreover, many works adopting point cloud maps reported in recent years have focused on 3D object detection (e.g., [98, 99, 100]). It is reasonably foreseeable that deep multimodal fusion of homogeneous and heterogeneous information sources can be a strong emphasis for intelligent mobility [22, 101] in the near future.

3. Fusion Methodologies

In this section, we provide a comprehensive review of deep multimodal fusion methods for semantic image segmentation. We highlight their benefits and drawbacks, providing interested readers with a complete overview of deep fusion strategies.

3.1. Taxonomy

In the early works [31, 95, 102], the classification of multimodal fusion strategies involves various taxonomic methods, including data fusion, early fusion, late fusion, intermediate fusion, and hybrid fusion. In this review, we explicitly
divide the deep multimodal fusion methods into early fusion, late fusion, and hybrid fusion, according to the fusion stage and motivation (see Figure 3).

Early fusion methods involve raw data-level fusion and feature-level fusion. The initial attempt of early fusion is to concatenate the raw data from different modalities into multiple channels. The learning model can be trained end-to-end using an individual segmentation network. Almost all the state-of-the-art segmentation networks are adaptable for such fusion strategy. Moreover, cross-modal interactions throughout the encoding stage, namely feature-level fusion, is also a distinctive manifestation of early fusion. For the sake of explanation, we denote the single segmentation network as $I$, $(x_1, x_2, ..., x_n)$ is a set of $n$ modalities as input, then the final prediction $y$ can be defined as:

$$y = I(x_1, x_2, ..., x_n).$$ (1)

On the contrary, late fusion methods aim to integrate multimodal feature maps at decision-level. More precisely, late fusion separately processes the multimodal data in different branches. During the decoding stage, all the feature maps computed by branches are mapped into a common feature space via fusion operations (e.g., concatenation, addition, averaging, weighted voting, etc.) [22], followed by a series of convolutional layers. Besides, we consider the common feature learned by the transformation network as a further refinement of decoding and prediction, some conventional intermediate fusion approaches (e.g., [103]) are therefore categorized into late fusion strategy in this review. Suppose that the segmentation networks $(I_1, \ldots, I_n)$ are used to process the multimodal
data \((x_1, x_2, ..., x_n)\) from different modalities, and \(P\) is the fusion operation as well as the following convolutional layers, the final output \(y\) can be formulated as:

\[
y = P(I_1(x_1), I_2(x_2), ..., I_n(x_n)).
\]  

(2)

Hybrid fusion methods are elaborately designed to combine the strengths of both early and late fusion strategies. Generally, the segmentation network accesses the data through the corresponding branch. Then more than one extra module is employed to compute the class-wise or modality-wise weights and bridge the encoder and decoder with skip connections. Therefore the hybrid fusion networks can adaptively generate a joint feature representation over multiple modalities, yielding a better performance in terms of accuracy and robustness.

3.2. Fusion strategies

Based on the common taxonomy of fusion strategy in Section 3.1, we systematically review the existing deep multimodal fusion networks for semantic image segmentation.

3.2.1. Early fusion

The first attempt at deep multimodal fusion was made by Couprie et al. [83] in 2013. This work presents an early fusion strategy via a simple concatenation of RGB and depth channels before feeding into a segmentation network. In the

Figure 5: RFBNet architecture with three bottom-up streams (RGB stream, depth stream, and interaction stream). Figure extracted from [105].

In case of similar depth appearance and location, this method shows positive results for indoor scene recognition. However, the simple concatenation of images provides limited help in multimodal feature extraction. The high variability of depth maps, to a certain extent, increase the uncertainty of feature learning.

To further explore semantic labeling on RGB-D data, FuseNet [84] was proposed in 2016 (see Figure 4). FuseNet is a clear example of incorporating the auxiliary depth information into an encoder-decoder segmentation framework. The abstract features obtained from the depth encoder are simultaneously fused to the RGB branch as the network goes deeper. Motivated by FuseNet, Ma et al. [104] proposed MVCNet to predict multi-view consistent semantics. Then Hung et al. [72] presented LDFNet that contains a well-designed encoder for the non-RGB branch, aiming to fully make use of luminance, depth, and color information. Recently, RFBNet [105] was proposed with an efficient fusion mechanism that explores the interdependence between the encoders (see Figure 5). The Residual Fusion Block (RFB), which consists of two modality-specific
residual units (RUs) and one gated fusion unit (GFU), was employed as the basic module to achieve the interactive fusion in a bottom-up way. Hu et al. [71] proposed a novel early fusion architecture based on attention mechanism, known as ACNet, which selectively gathers valuable features from RGB and depth branches. Besides, RTFNet [106] was particularly designed to fuse both RGB and thermal images by element-wise summation. Notably, average pooling and the fully connected layers in the backbone network was removed to avoid the excessive loss of spatial information.

3.2.2. Late fusion

As early as 2014, Gupta et al. [107] proposed a geocentric embedding for object detection and segmentation. The authors employed two convolutional neural network streams to extract RGB and depth features, respectively. The feature maps obtained from these two streams are combined by an SVM classifier.
at the late stage. Then the work by Li et al. \cite{108} addresses semantic labeling of RGB-D scenes by developing a Long Short-Term Memorized Context Fusion (LSTM-CF) model. This network captures photometric and depth information in parallel, facilitating deep integration of contextual information. The global contexts and the last convolutional features of RGB stream are fused by simply concatenating.

Besides, Wang et al. \cite{103} proposed a feature transformation network for learning the common features between RGB and depth branches. This fusion structure bridges the convolutional networks with the deconvolutional networks by sharing feature representation. Another typical late fusion network, mentioned as LFC, was presented by Valada et al. \cite{86}. This fusion architecture separately extracts multimodal features on the corresponding branch. The computed feature maps are summed up for joint representation, followed by a series of convolutional layers. Afterward, the authors extended the LFC method with a convoluted mixture of deep expert units, referred to as CMoDE \cite{109}. This deep fusion framework was inspired by the work \cite{112,113}, in which multimodal features are mapped to a particular subspace. An adaptive gating subnetwork is employed to produce class-wise probability distribution over the experts (see Figure \ref{fig:6}). In the work of LSD-GF, Cheng et al. \cite{110} proposed a gated fusion module to adaptively merge RGB and depth score maps according to their weighted contributions (see Figure \ref{fig:7}). More recently, CMnet \cite{111} made a new

3.2.3. Hybrid fusion

Previous studies have shown that simply concatenating multimodal features or fusing weighted feature maps at decision level may not be sufficient to meet the requirements of highly accurate and robust segmentation. The hybrid fusion strategy is proposed to combine the strengths of early fusion and late fusion as an alternative method.

In the early stages of hybrid fusion, Park et al. [114] extended the core idea of residual learning to deep multimodal fusion. This method, known as RDFNet, can effectively combine RGB-D features for high-resolution prediction through multimodal feature fusion blocks and multi-level feature refinement blocks. Afterward, Jiang et al. [115] introduced a fusion structure combining
a fully convolutional neural network of RGB-D (DFCN) and a depth-sensitive fully-connected conditional random field (DCRF). The DFCN module can be considered as an extension of FuseNet, while the DCRF module is used to refine the preliminary prediction. CFN is a cascaded feature network introduced by Lin et al. [117]. The feature maps generated by the RGB branch are used to match the image regions to complementary branches. Experimentally, the use of context-aware receptive field (CaRF) enables the fusion network to achieve a competitive segmentation result. Additionally, semantics-guided multi-level fusion [116], referred to as S-M Fusion, was proposed to learn the feature representation in a bottom-up manner (see Figure 8). This fusion strategy employed the cascaded Semantics-guided Fusion Block (SFB) to fuse lower-level features across modalities sequentially.

Moreover, Jiang et al. [118] described a residual encoder-decoder network for RGB-D semantic segmentation, named RedNet. The complementary features are fused into the RGB branch before upsampling. The skip-connection was used to bypass the spatial feature between the encoder and decoder. Instead of VGG, the residual module was applied as the basic building block. A more recent method addressed the issue of deep multimodal fusion using a Self-Supervised Model Adaptation module (SSMA) [70]. This fusion framework dynamically adapts the fusion of semantically mature multiscale representations. The latent
Figure 10: Individual semantic segmentation experts are combined modularly using different statistical methods. Figure extracted from [119]

joint representation generated from the SSMA block is integrated into decoder by two skip connections (see Figure 9). Arguably, the SSMA blocks enable the fusion model to exploit complementary cues from each modality-specific encoder, notably enhancing the discriminative power of feature representation.

3.2.4. Statistical fusion

As an alternative post-processing approach, statistical fusion is proposed to reduce the uncertainty of model and modalities at decision-level. Blum et al. [119] introduced statistical fusion methods to integrate deep learning-based segmentation prediction, including Bayes categorical fusion and Dirichlet fusion. The presented methods allow different training sets per expert (modality). Without extra training on aligned data, only a small subset is needed for calibration of the statistical models (see Figure 10). Combining multiple classifiers in a statistical way is not a new concept [120], but this work leads to an interesting research direction in the combination of deep learning and statistics.

3.2.5. Discussion

Deep multimodal fusion for scene understanding is a complex issue that involves several factors, including the spatial location of objects, the semantic
context of scenes, the effectiveness of fusion models, the physical properties of modalities, etc. The fusion strategies mentioned above follow different design concepts to tackle this challenge. Early fusion methods make an effort to optimally integrate information from multimodal sources during feature extraction. Namely, the representative features from complementary modality are automatically fused to the RGB branch or a gated branch at the early stage, while features are reconstructed via a common decoder. These works emphasize the importance of cross-modal information interaction. Late fusion methods generally map multimodal features into a common space at the decision level. In other words, the fusion model is trained to learn unimodal features separately. Thus, late fusion may offer more flexibility and scalability but lacks sufficient cross-modal correlation. Regarding hybrid fusion, such fusion strategy is elaborated to combine the strengths of early fusion and late fusion, achieving a more robust performance. However, the trade-off between accuracy and execution time should be carefully considered in architectural design.

This brings us to two main questions:

**When to Fuse:** Many deep multimodal fusion methods are extended from existing unimodal methods, or derived from other typical neural networks. In the former case, multiple unimodal segmentation networks are integrated into a composite end-to-end training model in early, late, or multi-level stages. Early fusion strategy allows stronger cross-modal information interaction, while late fusion shows more flexibility and scalability for implementation. Extensive experiments demonstrate that both low-level and high-level features are valuable to the final prediction. Multi-level fusion is helpful for segmentation model to learn representative features. Fusing multimodal contextual information in multi-level stages represents the current trend. Moreover, semantic guiding across layers, such as skip connections, can be effectively used to bridge early feature extraction and late decision making. The state-of-the-art method SSMA shows a typical example.
**How to Fuse:** Different from unimodal networks, deep multimodal fusion networks should consider multimodal information collaboration. Although deep learning-based methods learn representative features automatically, in many cases, multimodal input is likely to be imperfect. The redundancy, imbalance, uncertainty, and even contradiction of multimodal data may significantly affect the model’s performance. Simple fusion operations, such as summation and concatenation, provide limited help to generate optimal joint feature representations. Experiments indicate that several adaptive fusion methods make remarkable progress in terms of accuracy, such as attention-based networks. One potential reason is that such a learning model takes into account the contribution of multimodal features at multiple stages. Such fusion methods usually contain specific gating units that assign class-wise or modality-wise weights. One extreme case that should be noted is modality missing. Most of the existing deep fusion models can not work effectively when the supplementary modality is unavailable. Piasco et al. [121] offers some ideas based on learning with the privileged information paradigm to tackle this challenge. Otherwise, the trade-offs between accuracy/speed [122, 123, 22] or memory/robustness should be carefully considered in the architectural design. In order to provide readers a more intuitive understanding, we show more detailed evaluations in Section 5.

4. Datasets

Over the last decade, a large number of datasets have been proposed to meet the needs of deep learning-based methods. Since the quantity and quality of training data significantly affect the performance of learning models, many academic and research institutions have released several large-scale benchmark datasets for different scenarios. The creation of these well-annotated datasets actively promotes semantic scene understanding, which also facilitates the performance evaluation and inspires innovative approaches.
With the advent of multiple sensory modalities, numerous multimodal benchmark datasets have been released to the public successively. These datasets provide complementary properties of the same scene, such as geometric information, toward learning an improved feature representation. Figure 11 shows the accumulated dataset importance for image segmentation task since 2010. We observe that several large-scale datasets have emerged from 2015. Notably, PASCAL VOC 2012 [124] and Cityscapes [125] are two of the most popular datasets for semantic segmentation. As the representative RGB-D dataset, NYU-D [126] and SUN RGB-D [127] are frequently used for indoor scene understanding.

In the following parts, we provide a summary of current unimodal and multimodal datasets for semantic image segmentation. The aim is to grab the reader’s interest in multimodal scene understanding and facilitate the preliminary experiments on deep multimodal segmentation.

4.1. Popular datasets for image segmentation

As one of the earliest pixel-wise labeled image databases, MSRC dataset [128] was released for full scene segmentation. It consists of 591 images and 23 object classes. However, along with the development of deep learning techniques, small-scale datasets can not meet the demands of model training. PASCAL VOC dataset [124] is one of the most popular object segmentation datasets, which derived from the early stage competition: PASCAL Visual Object Classes (VOC) challenge. It provides thousands of images with pixel-level labeling. Up to now, it has been augmented to several additional datasets with a set of extra annotations, such as PASCAL-Context [129], PASCAL-Part [130], SBDB [131]. Another similar large-scale dataset is Microsoft COCO dataset [132], which contains 81 categories of objects, including 21 categories of PASCAL VOC. It covers complex everyday scenes and their contextual information. PASCAL VOC and COCO dataset are not only the most popular benchmarks for fully supervised segmentation but also frequently-used in weakly supervised learning for object segmentation.

Furthermore, several outdoor road scene datasets are constantly emerging.
during the last decade, e.g. CamVid [134], KITTI [135], Cityscapes [125], Mapillary Vistas [139], toward promoting the commercialization and advancement of autonomous driving technology [141]. To be specific, CamVid database is the first collection of fully segmented videos, captured from a moving vehicle. It provides over 700 manually labeled images of naturally complex driving scenes sampling from the video sequences. After that, KITTI Vision Benchmark was published to tackle various real-world computer vision problems, such as stereo, optical flow, visual odometry/SLAM, and 3D object detection. It consists of around 400 semantically annotated images recorded by RGB cameras, grayscale stereo cameras, and a 3D laser scanner.

During the past few years, Cityscapes dataset has been a strong performer in outdoor scene semantic segmentation. This high-quality dataset contains around five thousand high-resolution images with pixel-level annotations, recording the street scenes from 50 different cities. Also, Cityscapes is a superior multimodal segmentation dataset, containing precomputed depth maps of the same scenes. Besides, Mapillary Vistas dataset [139] provides 25,000 high-resolution images of street scenes captured from all over the world at various conditions regarding weather, season, and daytime. The images were annotated into 66 object categories, aiming to support the development of state-of-the-art methods for road scene understanding. More recently, for the sake of robustness and performance evaluation, WildDash [140] was released to the research community. This new benchmark provides standard data of driving scenarios under real-world conditions for a fair comparison of semantic segmentation algorithms. It is worth noting that RailSem19 [142] is the first public outdoor scene dataset for semantic segmentation targeting the rail domain, which is useful for rail applications and road applications alike.

We present a summary of the reviewed segmentation datasets in Table 4. Further information are provided, including numbers of classes, size of the database, and the type of scenes.

### 4.2. Multimodal datasets

Throughout the years, multimodal data are gaining the attention of researchers in various domains. The primary motivation for using multiple sensory modalities is to improve learning models’ performance by enriching the feature representation. Table 5 lists numerous multimodal datasets reviewed in this survey, providing valuable information such as their application scenarios and data information. Next, we describe the potential multimodal datasets for image segmentation in detail, covering RGB-D datasets, Near InfraRed datasets, thermal datasets, and polarization datasets. Multiple samples can be found in Table 6.

#### 4.2.1. RGB-D datasets

RGB-D cameras are widely used to augment the conventional color images with a depth map, which provides supplementary depth information about the distance of the object surface. Gupta et al. [107] proposed a method to encode horizontal disparity, height above ground, and the angle of the local surface normal into more efficient HHA images using raw depth images. Apart from
semantic segmentation, depth information also makes significant contributions to other scene understanding tasks, such as object detection \cite{107, 13} and pose estimation \cite{139}. The first row in Table \ref{table:datasets} illustrates RGB-D image examples sampling from the datasets reviewed in this part.

**Indoor scenes** One of the main difficulties for indoor scene segmentation is that object classes always come in various positions, shapes, and sizes. By taking advantage of RGB-D data, we can encode the pixel-level color and depth information of the same scene into a high-level feature representation. Such information fusion, to a certain extent, reduces the difficulty of indoor object recognition. NYUDv2 \cite{126} is an early RGB-D database containing 795 training images and 654 testing images with pixel-wise labels for 40 semantic categories. A Microsoft Kinect camera captured all the RGB and depth image pairs with favorable frame synchronization. This dataset aims to inform a structured 3D interpretation of indoor scenes, having become one of the most popular multimodal benchmarks so far. Another standard benchmark for indoor scene recognition is SUN RGB-D \cite{127}. It consists of around 10K RGB-D images with 37 indoor object classes. This dataset advances the state-of-the-art in all major scene understanding tasks and provides a fair comparison of deep multimodal fusion methods.

**Outdoor scenes** Unlike indoor scenes, the depth information of outdoor scenes is generally captured by stereo vision cameras or LiDAR due to Kinect’s poor performance in sunlight. As one of the segmentation benchmark datasets, Cityscapes consists of thousands of high-quality depth images of the same scene. These depth maps overcome the lack of depth information of objects for road scene recognition. In order to simulate different seasons, weather, and illumination conditions, several synthetic RGB-D datasets (e.g., SYNTHIA \cite{136}) are generated for driving scenes semantic segmentation.
4.2.2. Near-InfraRed datasets

Infrared imaging captured from multi-spectral cameras shows high contrast of natural and artificial objects [150, 151]. In the computer vision field, multi-spectral images make up the data in the non-visible light spectrum and help better understand the scene characteristics. For example, Freiburg Forest dataset [86] was created to tackle the semantic segmentation problem in forested environments. It consists of 366 aligned color, depth, and near-infrared images with six classes pixel-wise annotation. Due to the abundant presence of vegetation in the unstructured forest environment, this dataset provides enhanced NIR images (e.g., Normalized Difference Vegetation Index images, Enhanced Vegetation Index images) to ensure border accuracy. Besides, RANUS dataset [146] has been released to the public in 2018. It consists of 40k spatially-aligned RGB-NIR pairs for real-world road scenes, and thousands of keyframes are annotated with ground truth masks for ten classes: sky, ground, water, mountain, road, construction, vegetation, object, vehicle, and pedestrian.

Apart from semantic segmentation, multi-spectral images are also used in other computer vision tasks, including pedestrian detection [152, 153], face recognition [154], image dehazing [155, 156], video surveillance [157], to name a few.

4.2.3. Thermal datasets

Different from NIR images, thermal images are captured to recognize visible and invisible objects under various lighting conditions. The thermal imaging cameras are sensitive to all the objects that constantly emit thermal radiations [158]. The wavelength is generally detected up to 14µm. In the early years, thermal imaging cameras were invented for military uses. With the cost of sensors decreasing, many scene understanding tasks can now benefit from thermal information [106].

Tokyo Multi-Spectral [144] is the first large-scale color-thermal dataset for urban scene segmentation. It contains both visible and thermal infrared images captured in daily and night conditions. There are 1569 images manually
Figure 12: Reflection influence on polarimetry. (a) and (b) represent a zoom on the non-polarized and polarized area, respectively. Figure extracted from [164].

labeled to eight classes: car, person, bike, curve, car stop, guardrail, color cone, and bump. Then Shivakumar et al. [147] presented PST900, a dataset of 894 synchronized and calibrated RGB and thermal image pairs with pixel-level annotations across four distinct classes from the DARPA Subterranean Challenge. The long-wave infrared (LWIR) imagery was used as a supporting modality for semantic segmentation of subterranean scenes. These large-scale RGB-Thermal datasets broaden the research field of deep learning-based scene understanding, allowing for more in-depth exploration in poor visibility and adverse weather conditions.

4.2.4. Polarization datasets

As a universal phenomenon existing in natural scenes, polarimetric imaging is highly sensitive to the vibration pattern of the light [159]. In the natural environment, the polarisation of light is generally obtained by reflection or scattering. The polarization images carry crucial information of reflection surface, including object shape and surface material. As shown in [12] the micro-grid appears on the polarized surface and reveals an intensity change according to the polarizer affected. To tackle practical problems in computer vision, polarization images have been widely applied to object detection [160], image dehazing [161], depth estimation [162], [163].
Zhang et al. [111] released a small-scale segmentation dataset, known as POLABOT, that dedicates to the polarimetric imaging of outdoor scenes. Synchronized cameras collect hundreds of raw color, Near-InfraRed, and polarimetric images. All the images are manually labeled into eight classes according to the polarimetric characteristic of the scenes. For example, reflective areas such as windows and water are typically considered. More recently, Sun et al. [165] developed a multimodal vision system that integrates a stereo camera, a polarization camera, and a panoramic camera. The polarization camera is mainly used to detect specular materials such as glass and puddles, potentially dangerous for autonomous systems. Currently, the use of polarimetric data leads to new directions for deep multimodal fusion research. The polarimetric imaging offers great potential [166, 167] in scene understanding. For future perspectives, polarization cameras may be extremely valuable in autonomous driving [164, 165] and robotics [168, 169].

4.2.5. Critical challenges for multimodal data

Based on the review of multimodal image datasets, we summarized four critical challenges for multimodal data:

- **Data diversity**: different image sensors offer different representative features of the scene according to their physical properties. The accuracy and robustness of deep fusion models are closely related to the amount and variety of multimodal data. In addition to the multimodal types mentioned above, more data types are expected for complex tasks in computer vision.

- **Quantity and quality**: in order to meet the needs of deep learning model training, high-quality and large-scale multimodal image datasets are expected to cover various scenarios. Meanwhile, inaccuracy and noise should be considered in image processing.

- **Data alignment**: data collected by image sensors should be well aligned before training. Such alignment is often referred to as multi-modality calibration, and is an essential prerequisite for effective multimodal fusion.
Table 6: Examples of multimodal image datasets mentioned in Section 4.2. For each dataset, the top image shows two modal representations of the same scene. The bottom image is the corresponding groundtruth.

- **Dataset construction**: in the construction of multimodal datasets, we should think about 1) what kind of multimodal data do we need for the target scenarios? 2) what kind of multimodal data can provide more efficient information for specific tasks? 3) what kind of multimodal data is easier to collect in practice?

5. Evaluation

In this section, we report the evaluations of deep multimodal fusion methods that are mentioned in Section 3 on four benchmark datasets: SUN RGB-D [127], NYU Dv2 [126], Cityscapes [125], and Tokyo Multi-Spectral dataset [144]. We also conduct a direct comparison of different unimodal and multimodal
methods, aiming to demonstrate the necessity and importance of multimodal fusion approaches. All the results reported in this survey are collected from the original publications to ensure fairness.

5.1. Evaluation metrics and backbone networks

It is well known that how to evaluate the performance of a segmentation algorithm is a critical issue. A series of benchmark datasets promote the standardization of comparison metrics, providing a fair comparison of the state-of-the-art methods. More precisely, the performance of deep learning-based approaches can be reflected in all aspects [2], such as accuracy, memory usage, and runtime. Among these factors, accuracy may be the most common evaluation criteria to measure the performance of pixel-level prediction [170]. As a reference, a general analysis of accuracy metrics for classification tasks can be found in [171]. For multimodal image segmentation, the most popular metrics have no difference with unimodal approaches, including Pixel Accuracy (PA), Mean Accuracy (MA), Mean Intersection over Union (MIoU), and Frequency Weighted Intersection over Union (FWIoU), which are first employed in [40].

For the sake of explanation, we denote $n_{ij}$ as the number of pixels belonging to class $i$ which are classified into class $j$, and we consider that there are $n_{cl}$ classes, and $t_i = \sum_j n_{ij}$ is the numbers of pixel in class $i$. Then we can define these metrics as follows:

- **Pixel Accuracy**
  $$\frac{\sum_i n_{ii}}{\sum_i t_i}$$

- **Mean Accuracy**
  $$\frac{1}{n_{cl}} \sum_i \frac{n_{ii}}{t_i}$$

- **Mean Intersection over Union**
  $$\frac{1}{n_{cl}} \sum_i \frac{n_{ii}}{t_i + \sum_j n_{ji} - n_{ii}}$$

- **Frequency Weighted Intersection over Union**
  $$(\sum_k t_k)^{-1} \sum_i \frac{t_i n_{ii}}{t_i + \sum_j n_{ji} - n_{ii}}$$

Besides, many elaborated backbone networks, such as VGGNet [81], ResNet [82], and Xception [172], are widely used in a variety of segmentation network design [173]. These backbone networks not only extract effective semantic information and spatial details but also simplify the training.

The segmentation performance is generally affected by many factors, such as the preprocessing of data, fusion strategy, the choice of the backbone network, the practice of state-of-the-art deep learning technologies, etc. In the following, we summarize the evaluation results of multimodal fusion models and also analyze the influence of the algorithms and the multimodal data on the performances. Almost all of the models are pre-trained on a large-scale image database such as ImageNet [174].

5.2. Comparative results in terms of accuracy

We gathered quantitative results of the aforementioned fusion approaches from the corresponding papers and grouped them according to the benchmark datasets. The mean accuracy (%) and mean IoU (%) are the most reported metrics for a fair comparison. In the comparison tables, deep multimodal fusion methods are differentiated based on the used backbone network, the type of multimodal input, and the fusion strategy.

• SUN RGB-D dataset

Firstly, we report the experimental results on the indoor scene dataset, SUN RGB-D (see Table 7). Ten fusion methods and three unimodal methods are compared on this benchmark dataset. We observe that ACNet and CFN are the two top scorers with a mean IoU score of 48.1%. RedNet and RDFNet are not far behind with a score of 47.8% and 47.7%, respectively. In general, multimodal fusion methods are superior to unimodal methods, which have a similar backbone network.

Regarding the NYU Depth v2 dataset, which is also a typical indoor scene dataset with high-quality depth information, we select six methods to make a detailed comparison. Table 8 demonstrates the experimental results with 13 and 40 classes. ACNet is again the best performing method with a mean IoU score of 48.3% for 40 classes. Note that when the methods are evaluated on 13 classes only, the performances are higher because most challenging classes are not taken into account.

- Cityscapes dataset

Apart from the indoor scene datasets, we also show the segmentation results on a more challenging urban scene dataset, Cityscapes in Table 9. For this outdoor dataset, SSMA, as a typical hybrid fusion architecture, achieves the best performance with a mean IoU score of 83.94%. Moreover, we have observed that HHA representation provides more valuable properties than the original depth map. The multimodal fusion methods generally outperform the performance of the unimodal methods.

- Tokyo Multi-Spectral dataset

As shown in Table 10, we report the evaluation results on Tokyo Multi-Spectral dataset. Both visible spectral images and thermal images were used
in the fusion experiments. We also collect 4-channel early fusion methods for comparative study. The winner, RTFNet, achieves a maximum accuracy of 53.2% mean IoU. Notably, the segmentation accuracy is significantly increased by adding thermal infrared information. These results clearly show the effectiveness of multimodal data and the advancement of deep multimodal methods.

Based on the analysis of these results, we can draw some conclusions. First, depth information is the most commonly used supplementary information for multimodal image fusion. Most deep fusion methods report their results on the large-scale RGB-D datasets for both outdoor and indoor scene understanding. However, other types of multimodal datasets are of varying quality and lack further evaluation. The establishment of standard benchmark datasets is the premise of multimodal fusion study. Also, reported fusion methods employed various backbone networks, input size, and setups for the experiment, making fair performance comparisons difficult. Although many deep learning frameworks and libraries already exist, more multimodal toolkits are expected to facilitate multimodal fusion study.

In light of the reported results, we have observed that ACNet and SSMA achieved remarkable results on the RGB-D datasets. A major reason is that these methods adopt many advanced deep learning techniques, such as attention mechanism, multiscale feature aggregation, and skip connection. It can be seen that the development of deep learning technology is of great benefit to multimodal fusion. Moreover, it is worth noting that most methods focus on accuracy, which does not allow for a comprehensive evaluation of fusion models. Multiple metrics can also reflect the effectiveness of multimodal data, which is instructive to the construction of the multimodal data collection platform. In general, deep multimodal fusion methods require higher memory footprint and execution time. We report more detailed results in the following subsections.
Figure 13: Real-time and accuracy performance. Performance of SSMA fusion method using different real-time backbones on the Cityscapes validation set (input image size: $768 \times 384$, GPU: NVIDIA TITAN X).

Figure 14: Real-time and accuracy performance. Performance of different fusion methods on Tokyo Multi-Spectral dataset. (input image size: $640 \times 480$, GPU: NVIDIA 1080 Ti graphics card).
Table 11: Parameters and inference time performance. The reported results on the Cityscapes are collected from [70].

5.3. Real-time consideration

In order to evaluate the real-time performance of deep multimodal fusion networks, we summarized and provided the researchers with two sets of execution time comparisons, as shown in Figure [13][14]. Execution time or runtime, as an essential metric, obviously shows the learning model’s execution efficiency. Although this metric is easily ignored in the accuracy-centric algorithm optimization, it should be carefully considered in industrial-level applications, such as self-driving cars. The inference time is usually dependant on the hardware and backend implementation.

5.4. Memory footprint

Another performance indicator in the implementation aspect is memory usage. Large memory usage may increase computation time during training and testing. In this regard, proper use of deep learning frameworks, GPU acceleration, appropriate batch size, and compressed input may be beneficial for the model training. Table [11] demonstrates the comparisons on the number of parameters and inference time for various network architectures.

6. Conclusion

We have reviewed deep multimodal image segmentation from two aspects: fusion methodology and dataset. Multimodal image data, such as RGB-D image, Near-InfraRed image, thermal image, polarization image, are the primary concerns in this paper. To the best of our knowledge, this is the first review
paper that focuses on deep learning-based multimodal fusion for semantic image segmentation. In this work, we first described the development of multimodal fusion and provided the reader with relevant background knowledge to support text comprehension. Then we categorized 20 deep multimodal fusion methods into early fusion, late fusion, and hybrid fusion. We further discussed architectural design to explore the essentials of deep multimodal fusion. Besides, the existing image segmentation datasets are summarized, covering 12 current multimodal datasets. We made a comparative analysis of existing fusion approaches in terms of accuracy, execution time, and memory footprint, which evaluate the model performance on different benchmark datasets ranging from indoor scenes to urban street scenes.

In conclusion, deep multimodal fusion has gained much attention in recent years. Multimodal images captured from various sensory modalities provide complementary information of the scenes. The experimental results collected in this survey show the effectiveness of the deep multimodal fusion method. The state-of-the-art methods make efficient use of multimodal data, yielding an improved performance on semantic scene understanding. However, the optimal fusion strategy remains an open question in need of further exploration. As we know that deep learning-based artificial intelligence is gradually evolving from perception to cognitive intelligence, we expect deep multimodal fusion to facilitate this evolution and offer a host of innovations in the following years.
